## Executive Summary

Middle-market professional-services firms, which provide assurance, tax, and consulting, now contend with three pressures at once: assurance has lost its dominance of the profession's revenue mix even as the fixed cost of professional headcount has risen with advisory services now eclipsing assurance,<sup>1</sup> and a deepening accountant shortage has pushed staff compensation up by double digits.<sup>2</sup> The credentialed talent pipeline has contracted by nearly 42% in the past ten years, with new CPA candidates falling from 48,004 in 2016 to 28,082 in 2024.<sup>3</sup> The routine work that once trained the profession's next generation, reconciliation, testing, and audit support, is now absorbed by automation that replaces entry-level roles faster than the profession can rebuild them.

Firms have answered with two levers: offshoring converts fixed cost into lower-cost labor, yet it relocates production away from the credentialed judgment on which the engagement ultimately rests.<sup>4</sup> Generative AI lowers the cost of production, yet, applied without a governing structure, it risks degrading precisely the judgment the credential exists to protect.<sup>5</sup>

This paper proposes a third lever: a white-label analytical delivery model. Under this model the firm retains ownership of its data-acquisition and quality pipeline, while a contracted analytical production layer generates analysis at variable cost, under the firm's brand, and the firm's credentialed professionals review and sign the resulting deliverable. The arrangement resembles teleradiology, in which an imaging facility acquires and prepares the study, a contracted reader produces the initial interpretation, and an attending physician over-reads and signs the report.

Five mechanisms make the model durable. First, it converts fixed labor cost into variable cost, earning contribution margin on each deliverable rather than carrying headcount between engagements, and it offloads the software licensure costs onto the producer so the firm can concentrate its own stack on data preparation and credentialed review.

Second, it concentrates credentialed time at review and sign-off, preserving the economic value of the credential.

Third, it keeps the data pipeline in the firm's control and anonymizes its categorical attributes before handoff, so the analyst works on identity-free, encoded data, thereby protecting confidentiality and removing identity-driven bias from production.

Fourth, it reopens a paid on-ramp for credential-eligible professionals who lack the income and supervised experience required to finish their credentials.

Fifth, it institutionalizes the model through a belt-governed, human-in-the-loop AI structure, so that quality scales predictably rather than by the vigilance of any single person.

## 1. The Squeeze on the Modern Firm

The economics of a professional-services firm are straightforward to state but difficult to reconcile. Revenue is broadly a function of billable hours and realization; the primary input, credentialed labor, is fixed in the short run. Hiring a professional is a commitment that persists through the engagement pipeline's natural volatility, so a firm that must meet peak demand carries capacity through idle periods. Entry-level hiring is the traditional hedge: junior staff are inexpensive relative to credentialed practitioners and absorb the routine work that would otherwise consume billable senior time. That apprenticeship, in turn, manufactures the credentialed practitioners of the future.

Each leg of this arrangement is now under strain. New CPA candidates in the United States declined from 48,004 in 2016 to a low of 28,082 in 2024, and baccalaureate completions in accounting fell more than 10% in a single year even as enrollment recovered. Public accounting firms hired only 11,985 new graduates in 2024, and the organizations that once received the largest graduating classes have trimmed their campus recruiting. Concurrently, the work that justified those entry-level roles, tying out ledgers, performing routine reconciliations, and executing basic audit support, has migrated into systems that review entire datasets automatically. The profession's principal training ground is therefore shrinking at the same moment that its output is most needed.<sup>6</sup>

A further complication is that the two standard remedies each carry a structural cost. Offshoring lowers unit labor cost, but it moves production away from the credentialed judgment that the client purchases, and it does nothing to replenish the domestic credentialed pipeline on which the firm's long-term differentiation depends. Generative AI lowers the cost and raises the speed of production, but the evidence indicates that its benefits accrue most to senior, experienced professionals who treat the tool as a collaborator, while junior staff are more likely to accept its outputs uncritically. The technology augments expertise; it does not manufacture it. A firm that replaces its entry-level workforce with an ungoverned AI risks consuming the seed corn of its own future.

The consequence is a firm squeezed between a shifting revenue mix, a rigid cost base, and a credentialing pipeline that must be kept open without the entry-level roles that historically sustained it. The remainder of this paper describes a delivery model designed to relieve all three pressures simultaneously.

---

<sup>6</sup> (Zaki, 2025)

## 2. The Model

The white-label analytical delivery model organizes decision-support work into three tiers, each with a distinct owner and a distinct failure mode that the subsequent tier is designed to catch.

**Tier 0: Data acquisition and preparation.** The firm owns the entirety of the data pipeline. Its data-engineering and analytics group acquires, standardizes, and validates the source data, then produces a curated, governed, role-scoped extract for the analysis at hand, a

step that anonymizes the data by encoding every identifiable categorical attribute (product, entity, and counterparty names) into opaque tokens that disclose structure but not identity. The firm retains the mapping key, so the encoding is reversible only on the firm's side. No raw data leaves the firm's environment, and no analytical output is derived from anything other than the prepared extract. This tier establishes the trust boundary that makes the rest of the model defensible.

**Tier 1: Analytical production.** A contracted production layer receives the governed extract and produces the analysis: modeling, forecasting, valuation support, decision modeling, and the working papers that accompany them. This layer operates at variable cost, billed on completed deliverables rather than on retained headcount, and delivers under the firm's brand. The producer is credential-eligible, educated to the relevant standard but typically not yet credentialed, and works to a precise deliverable specification rather than to professional discretion. The producer supplies the analytical software stack used to generate that work, so the cost of analysis tooling sits with the producer rather than with the firm.

**Tier 2: Credentialed review and client delivery.** The firm's credentialed professionals, its CPAs, CFAs, and CMAs, review the deliverable, reconcile it against the source, assume responsibility for it, and deliver it to the client. Delivering through the credentialed layer keeps the client's trust where the accountability lies, rather than at the production layer that prepared the work. This is the shift in emphasis that gives the model its economic character: credentialed time moves from production to review, overriding the machine-generated volume rather than generating the volume itself.

The structure is best understood through its teleradiology analogue. An imaging facility staffs technologists to acquire and prepare the study, exactly as the firm's data-engineering group prepares the extract. A contracted radiologist produces the initial read, exactly as the production layer produces the analysis. An attending radiologist over-reads and signs the final report, exactly as the credentialed professional reviews and signs the deliverable. The patient, the client, receives a signed, accountable result at every point, while the scarce, high-value judgment is applied only where it is genuinely irreplaceable.

The analogy is not exact and should not be pressed beyond its utility. Where medical imaging removes identifiers, financial data is anonymized here by encoding them: categorical attributes become opaque tokens that disclose structure but not identity, reversible only through the mapping key the firm retains. Encoding does more than protect confidentiality; it removes identity from the production step, the basis of the bias control developed in Section 5. The principle holds: scarce interpretive judgment is conserved by separating acquisition, production, and sign-off, and by applying the scarcest resource only to the final act of accountability.

---

### 3. The Economics of Variable Capacity

A credentialed employee is a fixed cost within the planning horizon. Compensation, benefits, and recovery time are incurred whether or not an engagement requires the full measure of that professional's capacity. A firm that expands to meet a demand peak incurs the

entire cost of the hire but realizes only the revenue its current engagements support; a firm that declines to expand forgoes revenue it could otherwise have served. The result is the familiar pattern of professional services: capacity lags demand on the way up and overhangs revenue on the way down.

Practitioners within the profession recognize the same pressure and counsel against deepening it: Jennifer Wilson of ConvergenceCoaching, advising firm leaders on compensation, argues, *"You can keep from accelerating fixed costs by not getting so much of an increase on the base, but providing financial incentives, performance-based incentives, bonus money."*<sup>7</sup> What Wilson proposes for the individual, converting fixed base cost into incentive that tracks output, the white-label model applies to the engagement itself: fixed headcount becomes variable capacity, paid only when it produces.

Variable capacity inverts this relationship. Under a white-label arrangement the firm pays only for completed, accepted deliverables. There is no hire to carry through an idle quarter and no bench to fund. When demand rises, the production layer scales without a corresponding commitment of fixed cost; when demand falls, the engagement ends and the expense ends with it. The firm's cost structure becomes elastic in the precise sense that its revenue already is.

The second effect is on contribution margin. Each engagement is resold at the firm's market rate, while the cost of production is incurred at a lower rate, leaving a margin on every deliverable. Because the credentialed review tier is the same credentialed labor the firm already employs, now applied at higher leverage, the margin does not come from cutting rate or quality but from changing the mix of who does what. Credentialed hours move to the review and sign-off activities they alone can perform, and the margin reflects that higher-yield deployment.

A parallel conversion applies to the analysis software where the producer brings an independent AI stack to the engagement and absorbs its cost. A producer who can operate that stack profitably, converting tooling expense into accepted deliverables, earns the remaining margin; a producer who cannot is not fit for the role. Either outcome benefits the firm. The first supplies economical production; the second screens itself out before a hire is made. The firm therefore concentrates its own technical investment where it is irreplaceable: the data-preparation pipeline of Tier 0 and the credentialed review of Tier 2. For a middle-market firm already investing in its technical stack, that concentration is the point. Capital spent on acquisition, governance, and sign-off is capital spent on the work the credential and the client relationship require, rather than on a production environment that a contracted layer can furnish at its own expense.

Two further properties follow. First, the model is additive to, rather than competitive with, the existing practice: it is a capacity and margin mechanism, not a business-line displacement. Second, because the production layer is credential-eligible professionals rather than an interchangeable commodity, the arrangement compounds over time: the talent it develops becomes an input to the credentialed tier, which is the subject of Section 6.

#### 4. Protecting the Credential

The deepest objection to any labor-substitution model in a professional-services firm is that it dilutes the credential. This objection deserves to be taken seriously, because the credential is the source of the firm's pricing power and the client's confidence. The model proposed here does not dilute the credential; it concentrates it.

The economic value of a credential rests on its scarcity and on the judgment it attests to. A CPA, CFA, or CMA designation signifies both a verified body of knowledge and a supervised period of professional experience. Across the designations, that experience requirement is the binding constraint: CPA licensure requires one to two years of supervised experience depending on the pathway taken;<sup>8</sup> the CFA charter requires at least 4,000 hours of qualifying experience completed over no fewer than 36 months;<sup>9</sup> and the CMA requires two continuous years of relevant experience.<sup>10</sup>

When credentialed time is spent producing rather than reviewing, its scarcity is spent on work that a non-credentialed, credential-eligible producer can perform under specification, and none of it is left for the judgment that only the credentialed practitioner can exercise. The white-label model reverses this. The credentialed professional is moved to the point where the deliverable becomes an accountable opinion, and the credential is thereby spent only on what it alone authorizes. Rather than narrowing the credential's scope, the model enlarges its economic significance: the same credentialed hour now stands behind a greater volume of finished work, because it no longer competes with the hours required to produce that work in the first place.

Seen this way, the model is conservative rather than radical. It preserves the credentialed sign-off as the governance keystone of every engagement, and it makes the credential scarcer at the margin by increasing the leverage of each credentialed hour. The profession's concern about credential dilution is real; it is answered not by defending the status quo allocation of time but by reserving the credential for the judgment it exists to certify.

#### 5. Data Governance and Trust

Any model that introduces an external production layer raises an immediate and legitimate question: how does the firm retain control of confidentiality, quality, and the client relationship? The answer, in this model, is that the firm never relinquishes them.

The governing principle is that the firm owns the pipeline end to end. Raw data never leaves the firm's environment. The production layer receives only a curated, governed, role-scoped extract, one that is also anonymized, with every identifiable categorical attribute (product, entity, and counterparty names) encoded into an opaque token. The extract is prepared by the firm's data-engineering group for the specific engagement, and it contains no

more than the engagement requires. The analyst has no direct access to the source system, no ability to alter the extract, no ability to reverse the encoding, and no contact with the client. The deliverable itself is reviewed and signed by a credentialed professional before it is released, so the client's relationship remains with the firm at every point.

Anonymization carries a benefit beyond confidentiality: it controls for bias at the production step. Contextual information demonstrably biases expert judgment, even among practiced professionals: fingerprint examiners, exposed to task-irrelevant context about a case, changed the identifications they had previously reached from the evidence alone.<sup>11</sup> When an analyst can see that a given set of figures belongs to a particular product, division, or counterparty, that knowledge loads the analysis with the same expectation: a tendency to shade assumptions toward a known narrative, to treat a favored engagement more charitably, or to anchor a result to a desired outcome. Encoding categorical attributes into opaque tokens removes identity from the production tier, so the analyst reasons about structure and number rather than about who.

The credentialed reviewer, receiving the decoded deliverable, restores the context the encoding withheld: knowing which entity the figures belong to is precisely what permits the professional judgment, the entity-specific level-sets and weightings, that the credential exists to authorize. The sequence itself, judgment on the primary data first and contextual detail afterward, formalizes, in the professional-services setting, the linear sequential unmasking protocol of the forensic sciences<sup>12</sup> and the bias reduction that blinded review has been shown to achieve in grant evaluation<sup>13</sup>. Bias is thus controlled rather than eliminated, and it is controlled at the correct boundary: removed where it is unearned, and applied where it is earned.

This structure addresses the two specific risks that external capacity traditionally introduces. Confidentiality risk is bounded because the production layer sees only the scoped, anonymized extract, not the underlying system. Quality risk is bounded because the tiered review applies credentialed judgment and deterministic checks to every deliverable before it reaches the client, a control structure described in Section 7.

The teleradiology precedent is again instructive. The imaging facility does not outsource the acquisition of the study or the physician-patient relationship; it outsources only the interpretation, to a contracted reader whose work an attending physician then over-reads. The model proposed here preserves the same boundaries, with role-scoped curation and attribute encoding standing in for the imaging domain's removal of identifiers. Control of data in and delivery out remains with the firm; the contracted layer occupies only the interpretation in the middle

---

<sup>11</sup> (Dror, Charlton, & Péron, Contextual information renders experts vulnerable to making erroneous identifications, 2006)

<sup>12</sup> (Dror & Kukucka, 2021)

<sup>13</sup> (Hultgren, Patras, & Hicks, 2024)

## 6. Rebuilding the Talent Pipeline

The model's next mechanism answers the profession's most intractable problem: the credentialed pipeline is shrinking while the supervised-experience requirement that gated it remains in place.

The candidate who could become credentialed but is not yet, the analyst who has completed the relevant education but lacks either the income to fund the remaining steps or the supervised experience the credential requires, faces a bind. The credential demands supervised professional experience of one to two years, obtaining that experience demands a job, and the entry-level jobs that once provided it are precisely the roles now being thinned by automation and offshoring. The white-label model breaks the loop by converting the production tier itself into a paid, supervised on-ramp. Credential-eligible professionals perform credentialed-tier work under specification, receive income for it, and accrue the relevant experience, which, under the CFA framework, counts specifically when it produces "a work product that informs or adds value to" the decision-making process.<sup>14</sup>

The benefit to the firm is symmetrical. The production layer is not an anonymous bench that must be re-sourced each engagement but a developing cohort the firm can observe, evaluate, and selectively convert into credentialed staff. The firm gains a recruiting funnel whose candidates have already demonstrated quality on the firm's own work, at the firm's own standard, under the firm's own brand. The cost of selection, ordinarily the most expensive and least certain component of hiring, falls dramatically, because performance is observed before an offer is extended rather than inferred after one.

This mechanism is what distinguishes white-label delivery from plain offshoring. Offshoring exports the entry-level work and, with it, the credentialed pipeline's domestic future. White-label delivery retains the work inside the engagement, reasons about it at credentialed standards, and routes the developed talent back into the profession. The model does not merely tolerate the credential pipeline; it finances it.

---

<sup>14</sup> (CFA Institute, n.d.)

---

## 7. The Human-AI Governance Spine

The final mechanism converts an appealing structure into a dependable one. A white-label model works well in a single engagement; it scales only if quality, consistency, and accountability can be reproduced without relying on the vigilance of any one participant. The answer is a governance spine structured as a Six Sigma belt hierarchy, in which every role is paired with an AI counterpart and every handoff is validated deterministically before work proceeds.

The hierarchy comprises four levels. The **Master Black Belt** is the orchestrator, held by the credentialed decision-modeling leadership, and its AI counterpart performs the orchestration function of decomposition, routing, audit-trail maintenance, and escalation. The

**Black Belt** supervises quality across an engagement, held by the engagement or business-analysis lead, and its AI counterpart performs verification through a deterministic evaluation of each deliverable against its specification before it is passed upward. The **Green Belt** produces the analysis, held by the contracted analyst, and its AI counterpart performs the model-building and first-pass work. That counterpart is the producer's own stack, not the firm's.

The **Yellow Belt** is infrastructure alone, with no human occupant, and performs the automated data-quality and preflight validation on which the other tiers depend. The pairing of human and machine at each level is governed by a single principle: the AI produces the volume, the credentialed human owns the judgment, and deterministic checking owns the verification. The AI counterparts generate and check; they do not decide. Every handoff from a lower to a higher belt is mediated by a deterministic gate (a scope check, a recalculation, or an evaluation against the deliverable specification) that either passes the work or rejects it for correction. No judgment is delegated to a probabilistic process, and no expectation of human vigilance is left to chance.

This design responds directly to the finding that the benefits of AI in accounting accrue to experienced professionals who treat the tool as a collaborator, while less experienced users tend to accept its output uncritically.<sup>15</sup> The belt structure institutionalizes that difference: the machine produces and checks at scale, while the credentialed human sits at the point of judgment, and the deterministic gates catch the errors that probabilistic systems are known to introduce. The model deliberately keeps "that final judgment call" a human decision, while delegating to automation everything beneath it.

---

<sup>15</sup> (Murray, 2025)

---

## 8. Disintermediating the Marketplace

The customary route for a firm seeking contract analytical help runs through a freelance marketplace, of which Fiverr is the archetype. Such a platform is a market maker and little else: it neither produces the analysis, nor credentials the analyst, nor governs the data on which the analysis depends. It matches a buyer to a seller and levies its fee at the point of the match.

The fee is not incidental. Fiverr retains a 20% commission on every completed order and adds a service fee, typically 5.5% of the purchase, on the buyer's side;<sup>16</sup> across the marketplace, the platform's overall take runs near 28% of transaction value.<sup>17</sup> That margin is captured by neither the firm nor the analyst.

The terms of service lock the relationship in place after the fee is taken. Users may not offer, solicit, or accept any contract, engagement, or payment outside the site; a violation is a material breach that can permanently disable the account.<sup>18</sup> If Fiverr determines that a buyer has breached that undertaking, the buyer agrees to pay liquidated damages of US \$10,000, plus collection costs and attorney fees, at Fiverr's sole discretion. The same terms require buyers to engage sellers as independent contractors and forbid the buyer from exercising control, supervision, or direction over how the work is performed. All information and file exchanges must occur exclusively on the Site, and Fiverr provides no protection for users who interact

outside it. A professional-services firm that needs a supervised producer, a credentialed reviewer, and a governed extract cannot construct those conditions on a platform whose contract forbids them.

The marketplace further disciplines its suppliers toward the lowest price. Research on online freelance labour documents a reverse-auction dynamic in which freelancers compete by underbidding one another, a race to the bottom that lets clients pay less, and observes that the majority of freelancers on these platforms are located in low-cost markets, with India (26.7%), Bangladesh (14.7%), and Pakistan (12.1%) together accounting for more than half.<sup>19</sup> The analyst who sells there bids against a global pool and a near-unbounded catalog of substitutes, so the rational response is to lower the quote. The white-label producer faces neither condition: beyond the apprenticeship on-ramp described in Section 6, the producer is compensated against a deliverable specification at a credentialed tier, and the work accrues toward a credential rather than toward a cheaper bid.

For the firm, the marketplace is a poor sourcing surface for this kind of work. Its paying-buyer base is contracting with active buyers falling from roughly 4.2 million in 2023 to 3.1 million in 2025, a decline of 13.6% in the most recent year, despite monthly visits running near 80 million; its design offers none of the properties on which the white-label model rests: no data governance, no credentialed review, no role-scoped, anonymized extract. A firm that sources through the marketplace must therefore construct those safeguards itself, afterward, at its own expense. The white-label model reverses the sequence, installing governance, credentialing, and the anonymized extract before the engagement begins.

Removing the intermediary thus leaves no gap. It recovers the value the intermediary was extracting and reapportions it to the two parties the transaction actually involves: margin on the firm's side, and a sustained, credential-earning rate on the analyst's side, in place of a market maker's fee and the pricing war it provokes.

---

<sup>16</sup> (Fiverr, n.d.)

<sup>17</sup> (Skillademia, 2026)

<sup>18</sup> (Fiverr, n.d.)

<sup>19</sup> (Oprins, 2024)

---

## 9. From Pilot to Scale

The model is best adopted incrementally rather than declared. A single engagement provides the demonstration that de-risks everything that follows.

The first stage selects one engagement with a well-bounded, repeatable analytical deliverable and runs it through the three tiers in miniature: the firm's data-engineering group prepares the extract, a contracted producer completes the analysis to specification, and a credentialed professional reviews and signs it. The second stage standardizes what the pilot reveals: the deliverable specification, the handoff contract, and the deterministic gates, so that the second engagement does not reinvent the first. The third stage shifts credentialed time up

the value stack, consolidating review and sign-off responsibility at the credentialed tier and converting the production layer to variable cost. The fourth and final stage codifies the economics, so that the margin, the quality standard, and the pipeline mechanics become a repeatable operating model rather than a set of heroic individual acts.

Each stage has a defined exit. The pilot exits when the credentialed reviewer can certify a deliverable produced outside the firm as confidently as one produced within it. Standardization exits when a new producer can be brought up to passing quality with demonstrable speed. The shift up-stack exits when credentialed time is documented to have moved from production to review across a representative engagement. Codification exits when the economics and controls are documented well enough to survive a change of personnel. The model does not ask the firm to commit to its conclusion before it has observed its premise.

---

## 10. Governance, Compliance, and Risk

A balanced treatment must acknowledge the model's limits and the alternatives it declines.

The principal counterargument is that the model is unnecessary, because lower-cost alternatives already exist. Offshoring delivers lower-cost production at scale; in Deloitte's 2024 Global Outsourcing Survey, 80% of executives plan to maintain or increase their third-party outsourcing, with cost reduction still among the leading drivers.<sup>20</sup> Generative AI can lower the cost and raise the speed of production without any human producer at all. The freelance marketplace of Section 8 offers a third route, one that supplies a producer while supplying none of the governance, credentialing, or trust boundary the engagement requires. Each option lowers cost; none addresses the model's central problem, which is the preservation of credentialed judgment and the domestic pipeline that produces it. Offshoring, ungoverned AI, and the freelance marketplace all move judgment away from the credential; white-label delivery reduces cost while keeping the credential at the point of decision.

Further risks are real and must be managed rather than minimized. Independence and confidentiality require written, audited controls over the data pipeline and the scoping of each extract; these are the trust boundary described in Section 5 and cannot be assumed. The supervision boundary must be explicit, so that the credentialed reviewer's role is understood as review and sign-off rather than automatic adoption of the producer's work. Professional and regulatory obligations vary by jurisdiction and by designation, and a model that claims to protect a credential must be implemented in a way that respects the specific licensing and experience rules of the jurisdictions in which it operates.

None of these risks are disqualifying; each is a control to be built. The model's defensibility rests on the firm's ownership of data and sign-off, on the deterministic gates that mediate every handoff, and on a treatment of the credentialed reviewer as the author of the accountable opinion rather than a rubber stamp. Where those controls are present, the model is compatible with the obligations a firm already carries.

---

<sup>20</sup> (Coronado, 2024)

## Conclusion

Professional-services firms are pressed between a shifting revenue mix, a rigid credentialed cost base, and a pipeline that is shrinking at the moment its output is most needed. The two familiar remedies, offshoring and generative AI, relieve cost but strain the judgment and the pipeline on which the firm's long-term value depends.

The white-label analytical delivery model is a third lever, distinguished by what it refuses to compromise. It converts fixed cost to variable cost, so the firm pays for capacity only when it produces, and it locates the analysis stack with the producer, so the firm's own software can be reserved for preparation and review. It concentrates the credential at review and sign-off, so credentialed time is spent only on what it alone authorizes. It keeps data acquisition and client delivery in the firm's control, so nothing of consequence leaves the firm. It reopens a paid on-ramp for the credential-eligible professionals the pipeline has stranded. And it institutionalizes all of this through a belt-governed, human-in-the-loop AI spine, so that quality scales by design rather than by vigilance.

The model does not ask a firm to choose between margin and judgment, or between automation and the development of its people. It offers a structure in which the AI produces the volume, the credentialed human owns the judgment, and the deterministic checks own the verification, so that the firm can expand decision-support capacity without fixed headcount, without diluting the credential, and without surrendering control.
